# A New Active Visual System for Humanoid Robots

De Xu, Member, IEEE, You Fu Li, Senior Member, IEEE, Min Tan, and Yang Shen

Abstract—In this paper, a new active visual system is developed, 4 which is based on bionic vision and is insensitive to the property 5 of the cameras. The system consists of a mechanical platform 6 and two cameras. The mechanical platform has two degrees of 7 freedom of motion in pitch and yaw, which is equivalent to the 8 neck of a humanoid robot. The cameras are mounted on the 9 platform. The directions of the optical axes of the two cameras 10 can be simultaneously adjusted in opposite directions. With these 11 motions, the object's images can be located at the centers of the 12 image planes of the two cameras. The object's position is deter-13 mined with the geometry information of the visual system. A more 14 general model for active visual positioning using two cameras 15 without a neck is also investigated. The position of an object can 16 be computed via the active motions. The presented model is less 17 sensitive to the intrinsic parameters of cameras, which promises 18 more flexibility in many applications such as visual tracking with 19 changeable focusing. Experimental results verify the effectiveness 20 of the proposed methods.

21 *Index Terms*—Active vision, bionic vision, humanoid robot, 22 positioning, visual system.

#### I. Introduction

24 THE PINHOLE model for cameras has been widely used in robot visual systems [1]. Generally, the parameters in 26 the camera model need to be calibrated to perform visual mea-27 surement or control. The inherent parameters of a camera, such 28 as the focus length, the principal point, and the magnification 29 coefficients from the imaging plane coordinates to the image 30 coordinates, are referred to as intrinsic parameters. The external 31 parameters such as the relative positions and orientations of 32 cameras are the extrinsic parameters. In many applications such 33 as visual positioning [2], [3] and motion estimation [4], only 34 the intrinsic parameters are of concern. On the other hand, the 35 intrinsic and extrinsic parameters are important in applications 36 with stereovision [5]. Up to now, the calibration for intrinsic 37 parameters of a camera [5] has been well studied including the 38 use of a special planar pattern [6], [7]. Although the methods 39 are effective, their calibrating process is, in general, tedious and 40 prone to errors.

To reduce the influence of the errors in camera calibration 41 on visual control, some researchers developed the image-based 42 visual servoing (IBVS) [1], [8] and hybrid visual servoing 43 methods [9]. The camera's parameters are not separately es- 44 timated in IBVS, but included in the estimation of the image 45 Jacobian matrix. With the camera parameters in the feedback 46 loop of the image features, the influence of errors in camera 47 calibration is reduced, but still exists.

Self-calibrating methods have been studied to eliminate the 49 need for special patterns and to increase the adaptability of 50 the visual system. One category of such calibration is based 51 on special motions of the camera [10]. Another is based on 52 the environment information such as parallel lines [11]-[13]. 53 Recently, attention has focused on uncalibrated visual servoing 54 (UCVS). In fact, the cameras in some UCVS systems are self- 55 calibrated [14]. The methods in some UCVS systems belong 56 to IBVS since cameras' parameters are not individually esti- 57 mated, but combined into the estimation of the image Jacobian 58 matrix [15]. Some researchers pursue the visual control without 59 camera parameters [16]-[18]. For instance, Shen et al. [16] 60 limited the workspace of the end-effector on a plane that is 61 vertical to the optical axis of the camera to eliminate the camera 62 parameters in the image Jacobian matrix. A visual control 63 method based on the epipolar line and the cross ratio invariance 64 was developed with two uncalibrated cameras in [18]. It did 65 not use camera parameters, and the working space of the end- 66 effector was in 3-D Cartesian space. However, this method was 67 limited to approaching task.

The results of traditional visual measurements are dependent 69 much on cameras' parameters, particularly the intrinsic param-70 eters. In general, the focus of a camera is fixed, which heavily 71 limits its flexibility in practical applications such as visual 72 tracking. In addition, a camera needs to be calibrated before it 73 is to be used for a new task. Obviously, the visual measurement 74 and control methods that are insensitive to camera intrinsic 75 parameters would be much more flexible and convenient to use 76 than traditional ones.

The motivation of this paper is to develop a new visual 78 system that is insensitive to the property of the cameras. An 79 active visual system as well as its positioning method is de- 80 signed to conduct visual measurement in the center areas of the 81 cameras, which is insensitive to the intrinsic parameters. With 82 the geometry information of our visual system, the position of 83 an object can be determined even if the intrinsic parameters 84 of the cameras are not available. The rest of this paper is 85 organized as follows. The bionic visual models are introduced 86 in Section II. One model is for the humanoid robot with a head 87 of two degrees of freedom (DOFs). Another is a general model 88 for any mobile robots. In Section III, the relative positioning for 89 multiple objects is discussed. Section IV investigates the errors 90

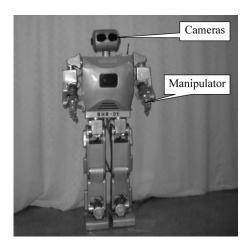

Fig. 1. Structure of a humanoid robot.

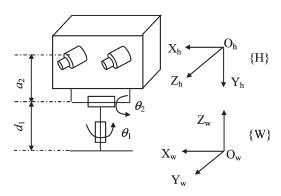

Fig. 2. Sketch of the neck and the head.

91 for the two proposed models. The calibration method for the 92 initial directions of the optical axes of the cameras is provided 93 in Section V. The experimental results are given in Section VI. 94 Finally, this paper is concluded in Section VII.

#### II. BIONIC VISUAL MODEL

#### 96 A. Visual System for a Humanoid Robot

95

A humanoid robot has a typical configuration of the visual system as follows [19]. There are two cameras mounted on the head of the robot, which serve as the eyes. An eye-to-hand too system is formed with these two cameras and a manipulator. The head has two DOFs: yaw and pitch [20]. The cameras and DOFs, the head can be taken as an eye-in-hand system. With the two DOFs, the head can work as an active vision system (Fig. 1). The sketch of the neck and the head of a humanoid robot is given in Fig. 2. The first joint is responsible for yawing, and the second one for pitching. The world frame W for the head to sassigned at the connect point of the neck and the body. The head frame H is assigned at the midpoint of the two cameras.

#### 109 B. Bionic Visual Model for a Humanoid Robot

The two cameras can simultaneously yaw in opposite di-111 rections to stare at an object. In the initial state of the two 112 cameras, they are well mounted so that their optical axes are 113 almost parallel. Therefore, the line connecting the two cameras 114 is on the plane formed by the two optical axes. The following

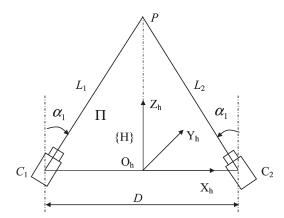

Fig. 3. Principle of visual positioning.

symbols are defined to describe the cameras (see also Fig. 3). 115  $L_1$  denotes the optical axis of a camera  $C_{a1}$ .  $C_1$  is its optical 116 principal point.  $L_2$  and  $C_2$  indicate the optical axis and the 117 optical principal point, respectively, of another camera  $C_{a2}$ .  $\Pi$  118 denotes the plane formed by  $L_1$  and  $L_2$ . The position of a point 119 P is expressed as  $[x_h,y_h,z_h]$  in frame H, and  $[x_w,y_w,z_w]$  in 120 frame W.

For a point P, it can be adjusted to be on the plane  $\Pi$  122 with the change in  $\theta_2$ . Then, it can be on the perpendicular 123 bisector of line  $C_1C_2$  on the plane  $\Pi$  with the adjustment of 124  $\theta_1$ . With simultaneous yawing in opposite directions for the 125 two cameras, the images of point P can be placed at the center 126 positions of the image planes of the two cameras.

The transformation matrix from frame W to H is given in (1) 128 according to the Denavit–Hartenberg (D-H) parameters model, 129 where  $d_1$  and  $a_2$  are the D-H parameters of the neck's joints.  $\theta_1$  130 and  $\theta_2$  are the joint angles of the two joints.

$${}^{w}T_{h} = \begin{bmatrix} \cos\theta_{1} & -\sin\theta_{1}\sin\theta_{2} & -\sin\theta_{1}\cos\theta_{2} & a_{2}\sin\theta_{1}\sin\theta_{2} \\ \sin\theta_{1} & \cos\theta_{1}\sin\theta_{2} & \cos\theta_{1}\cos\theta_{2} & -a_{2}\cos\theta_{1}\sin\theta_{2} \\ 0 & -\cos\theta_{2} & \sin\theta_{2} & a_{2}\cos\theta_{2} + d_{1} \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

$$(1)$$

Assume that the yawing angles of the two cameras are equal 132 to  $\alpha_1$ . It is known from Fig. 1 that the coordinates of point P in 133 frame H are zero in the axes  $X_h$  and  $Y_h$ . The coordinate in the 134 axis  $Z_h$  is

$$z_h = D/(2\tan\alpha_1) \tag{2}$$

140

where D is the distance between the optical principal points of 136 the two cameras, and  $\alpha_1$  is the yawing angle.

The position of point P in frame W can be calculated with 138 (3) according to (1) and (2), i.e.,

$$\begin{bmatrix} x_w \\ y_w \\ z_w \\ 1 \end{bmatrix} = {}^wT_h \begin{bmatrix} x_h \\ y_h \\ z_h \\ 1 \end{bmatrix} = \begin{bmatrix} -z_h \sin \theta_1 \cos \theta_2 + a_2 \sin \theta_1 \sin \theta_2 \\ z_h \cos \theta_1 \cos \theta_2 - a_2 \cos \theta_1 \sin \theta_2 \\ z_h \sin \theta_2 + a_2 \cos \theta_2 + d_1 \\ 1 \end{bmatrix}. \tag{3}$$

# C. General Bionic Visual Model

The general bionic visual model is designed for the robots 141 without the neck. It consists of two cameras simultaneously 142

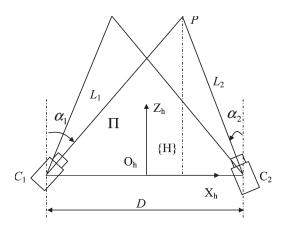

Fig. 4. Principle of visual positioning with the general model.

143 yawing in opposite direction. In such a case, it is impossible 144 to place the images of a point P at the center positions of the 145 image planes of the two cameras at the same time. However, 146 its horizontal imaging coordinates can be equal to those of 147 the image plane centers of the two cameras separately. The 148 cameras are simultaneously yawed in two steps, in which the 149 coordinates of the image plane centers are taken as the desired 150 values. In the first step, the horizontal imaging coordinate of 151 point P in camera  $C_{a1}$  is adjusted to the desired value, and the 152 image coordinates of point P in camera  $C_{a2}$  are recorded. In 153 the second step, the horizontal imaging coordinate of point P 154 in camera  $C_{a2}$  is adjusted to the desired value, and the image 155 coordinates of point P in camera  $C_{a1}$  are recorded. The yawing 156 angles in the two steps are recorded as  $\alpha_1$  and  $\alpha_2$ . In the  $X_h Z_h$  157 plane, the geometric relation is shown in Fig. 4.

158 From the geometric relation in Fig. 4,  $z_h$  and  $x_h$  are com-159 puted as follows:

$$z_h = D/(\tan \alpha_1 + \tan \alpha_2) \tag{4}$$

$$x_h = z_h \tan \alpha_1 - D/2 \tag{5}$$

160 where  $\alpha_1$  is the yawing angle in the first step, and  $\alpha_2$  is the 161 yawing angle in the second step.

For camera  $C_{a1}$ , the relation between the coordinates in im-163 age and Cartesian space can be expressed as follows according 164 to the pinhole model with four intrinsic parameters:

$$\begin{cases} u_{11} - u_{10} = k_{x1} \frac{x_{c1}}{z_{c1}} \\ v_{11} - v_{10} = k_{y1} \frac{y_{c1}}{z_{c1}} \end{cases}$$
 (6)

165 where  $[u_{11},v_{11}]$  are the image coordinates of point P in camera 166  $C_{a1}$  in the second step.  $[u_{10},v_{10}]$  are the image coordinates of 167 the optical principal point, and  $u_{10}$  is used as the desired image 168 coordinate in the first step.  $[x_{c1},y_{c1},z_{c1}]$  are the Cartesian 169 coordinates of point P in the frame of camera  $C_{a1}$  in the second 170 step.  $k_{x1}$  and  $k_{y1}$  are the scale factors from imaging plane 171 coordinates to the image coordinates.

72  $y_{c1}$  can be deduced from (6) with the elimination of  $z_{c1}$ , i.e.,

$$y_{c1} = \frac{v_{11} - v_{10}}{u_{11} - u_{10}} \frac{k_{x1}}{k_{y1}} x_{c1} \approx \frac{v_{1d}}{u_{1d}} x_{c1}$$
 (7)

173 where  $u_{1d} = u_{11} - u_{10}$  and  $v_{1d} = v_{11} - v_{10}$ .

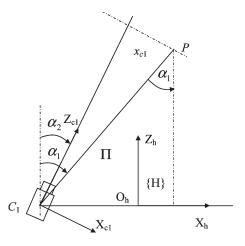

Fig. 5. Geometric relation for a camera.

From the geometric relation as shown in Fig. 5,  $x_{c1}$  can be 174 expressed with  $z_h$ , i.e.,

$$x_{c1} = \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} z_h \tag{8}$$

where  $\alpha_1$  and  $\alpha_2$  are same as described in (4).

Applying (8) to (7), 
$$y_{c1}$$
 can be obtained, i.e.,

$$y_{c1} \approx \frac{v_{1d}}{u_{1d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} z_h. \tag{9}$$

Similarly,  $y_{c2}$  can be obtained as follows for camera  $C_{a2}$ :

$$y_{c2} \approx \frac{v_{2d}}{u_{2d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_2} z_h \tag{10}$$

where  $u_{2d}=u_{21}-u_{20}$  and  $v_{2d}=v_{21}-v_{20}$ .  $[u_{21},v_{21}]$  are the 179 image coordinates of point P in camera  $C_{a2}$  in the first step. 180  $[u_{20},v_{20}]$  are the image coordinates of the optical principal 181 point of camera  $C_{a2}$ , and  $u_{20}$  is used as the desired image 182 coordinate of point P in the second step.  $y_{c2}$  is the Cartesian 183 coordinate of point P on the  $Y_{c2}$ -axis in the frame of camera 184  $C_{a2}$  in the first step.

The average of  $y_{c1}$  and  $y_{c2}$  is taken as the coordinate  $y_h$ , i.e., 186

$$y_h = (y_{c1} + y_{c2})/2.$$
 (11)

The position of a point P in world frame W is easy to be 187 obtained for the robot with a neck of two DOFs via coordinate 188 transformation after its position in frame H is obtained [see also 189 (3)]. This is very helpful for a robot to track an object in a large 190 range.

#### III. RELATIVE POSITIONING FOR MULTIPLE OBJECTS 192

Suppose that there are multiple objects in the common view 193 field of two cameras. One object is selected as reference, and it 194 is measured using the method in Section II-C. The symbols  $L_{11}$  195 and  $L_{12}$  denote optical lines in two steps for camera  $C_{a1}$ , and 196 the symbols  $L_{21}$  and  $L_{22}$  for camera  $C_{a2}$ . The view fields can 197 be divided into 12 areas from  $S_1$  to  $S_{12}$ , as shown in Fig. 6, with 198 lines  $L_{11}$ ,  $L_{12}$ ,  $L_{21}$ , and  $L_{22}$ , and the  $Z_h$ -axis. It is found that 199 the areas  $S_1$  and  $S_2$  are distinguished with the  $Z_h$ -axis, so are 200

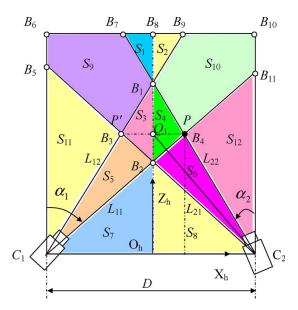

Fig. 6. Areas division in relative positioning.

201 the areas  $S_3$  and  $S_4$ , and  $S_7$  and  $S_8$ . The other areas are divided 202 by optical lines  $L_{11}$ ,  $L_{12}$ ,  $L_{21}$ , and  $L_{22}$ .

Four frames of images are captured at the two measuring 204 positions with yawing angles  $\alpha_1$  and  $\alpha_2$  for the two cameras. 205 The image coordinates are indicated with  $[u_{ijk}, v_{ijk}]$  for object 206 k in the image j of camera i. The area in which object k 207 locates can be determined with the image coordinates of object 208 k and the optical principal points, i.e.,  $[u_{ijk}, v_{ijk}]$  and  $[u_{i0}, v_{i0}]$ , 209 i = 1, 2, j = 1, 2. The division can be concluded as given in 210 (12) from Fig. 6, i.e.,

$$S \in \begin{cases} S_{1}, & \text{if } u_{12k} < u_{10}, \ u_{22k} > u_{20}, \ |u_{12kd}| > |u_{22kd}| \\ S_{2}, & \text{if } u_{12k} < u_{10}, \ u_{22k} > u_{20}, \ |u_{12kd}| < |u_{22kd}| \\ S_{3}, & \text{if } u_{11k} < u_{10}, \ u_{12k} > u_{10}, \ u_{21k} > u_{20}, \\ & u_{22k} < u_{20}, |u_{11kd}| > |u_{21kd}| \\ S_{4}, & \text{if } u_{11k} < u_{10}, \ u_{12k} > u_{10}, \ u_{21k} > u_{20}, \\ & u_{22k} < u_{20}, |u_{11kd}| < |u_{21kd}| \\ S_{5}, & \text{if } u_{11k} < u_{10}, \ u_{12k} > u_{10}, \ u_{21k} < u_{20} \\ S_{6}, & \text{if } u_{11k} > u_{10}, \ u_{21k} > u_{20}, \ u_{22k} < u_{20} \\ S_{7}, & \text{if } u_{11k} > u_{10}, \ u_{21k} < u_{20}, \ |u_{11kd}| < |u_{21kd}| \\ S_{8}, & \text{if } u_{11k} > u_{10}, \ u_{21k} < u_{20}, \ |u_{11kd}| > |u_{21kd}| \\ S_{9}, & \text{if } u_{12k} < u_{10}, \ u_{21k} > u_{20}, \ u_{22k} < u_{20} \\ S_{10}, & \text{if } u_{11k} < u_{10}, \ u_{12k} > u_{10}, \ u_{22k} > u_{20} \\ S_{11}, & \text{if } u_{12k} < u_{10}, \ u_{21k} < u_{20} \\ S_{12}, & \text{if } u_{11k} > u_{10}, \ u_{22k} > u_{20} \end{cases}$$

$$(12)$$

211 where S is the area in which the object k locates.  $u_{ijkd} = 212 \ u_{ijk} - u_{i0}$ .

After the area in which the object k locates is determined, 214 the approximate position in the area can be estimated according 215 to the image coordinates  $u_{ijk}$ . In addition, the areas  $S_3$  and  $S_4$  216 can be divided into subareas using auxiliary point  $Q_1$ , which is 217 the intersection of line  $B_3B_4$  and the  $Z_h$ -axis. The angle  $\beta$  is 218 defined as  $\angle B_2C_2Q_1$ , which is given as follows:

$$\beta = \text{atan}(2z_h/D) + \alpha_1 - \pi/2.$$
 (13)

The horizontal coordinate of point  $Q_1$  in the first image of 219 camera  $C_{a2}$  can be estimated as follows since it is in proportion 220 to the imaging angle:

$$u_{21q} = u_{211}\beta/(\alpha_1 - \alpha_2) \tag{14}$$

where  $u_{21q}$  and  $u_{211}$  are the horizontal coordinates of point  $Q_1$  222 and the reference object in the first image of camera  $C_{a2}$ .

Similarly,  $u_{12q}$ , the horizontal coordinate of point  $Q_1$  in the 224 second image of camera  $C_{a1}$ , can be estimated. Then, the areas 225 such as  $S_3$ ,  $S_4$ ,  $S_5$ ,  $S_6$ ,  $S_9$ , and  $S_{10}$  can be further divided using 226  $u_{21q}$  and  $u_{12q}$ .

The error analysis is focused on the errors caused by the 229 yawing mechanism for the two cameras.

For the model in Section II-B, the relative error can be 231 calculated via the derivative of (2), i.e.,

$$dz_h/z_h = dD/D - 2d\alpha_1/\sin(2\alpha_1) \tag{15}$$

where dD is the error in D, and  $d\alpha_1$  is the error in  $\alpha_1$ . 233 Generally,  $\alpha_1 \neq 0$ . In the case of very little  $\alpha_1$ ,  $\sin(2\alpha_1)$  will 234 converge to  $2\alpha_1$ . Thus, (15) can be rewritten as 235

$$dz_h/z_h \approx dD/D - d\alpha_1/\alpha_1 \le |dD/D| + |d\alpha_1/\alpha_1|.$$
 (16)

From (16), it is easy to find that the relative error in  $z_h$  is 236 proportional to relative errors dD/D and  $d\alpha_1/\alpha_1$ . For example, 237 when the relative errors in D and  $\alpha_1$  are 1%, the relative error 238 in  $z_h$  is not more than 2%.

For the model in Section II-C, the relative error can be 240 calculated via the derivative of (4), i.e.,

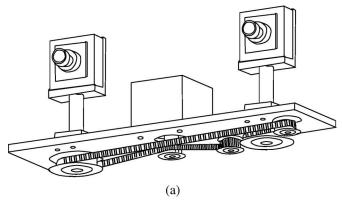

$$\frac{dz_h}{z_h} = \frac{dD}{D} - \frac{(\cos\alpha_2/\cos\alpha_1)d\alpha_1 + (\cos\alpha_1/\cos\alpha_2)d\alpha_2}{\sin(\alpha_1 + \alpha_2)}.$$
(17)

In general,  $\alpha_1 > 0$  and  $\alpha_2 > 0$ ; therefore,  $\alpha_1 + \alpha_2 \neq 0$ . If 242  $\alpha_1$  and  $\alpha_2$  are small enough, then (17) can be rewritten as 243 follows:

$$dz_h/z_h \approx dD/D - d(\alpha_1 + \alpha_2)/(\alpha_1 + \alpha_2)$$
  
 
$$\leq |dD/D| + |d(\alpha_1 + \alpha_2)/(\alpha_1 + \alpha_2)|.$$
 (18)

If  $d\alpha_1$  and  $d\alpha_2$  are taken as the same, then (17) degenerates 245 to (16).

The term  $|d(\alpha_1 + \alpha_2)/(\alpha_1 + \alpha_1)|$  would be large if the 247 errors  $d\alpha_1$  and  $d\alpha_2$  are large since the optical axes of the two 248 cameras are not parallel in the initial state. In the initial state, the 249 nonparallel axes can be taken as the results that the optical axes 250 are yawed with initial angles. Hence, it is necessary to calibrate 251 the initial angles of the optical axes relative to the  $Y_h Z_h$  plane. 252 In fact, the influence of the principal point on the errors of  $z_h$  253 can be taken in the same way as for that of the initial angles and 254 can be reduced via initial angle calibration.

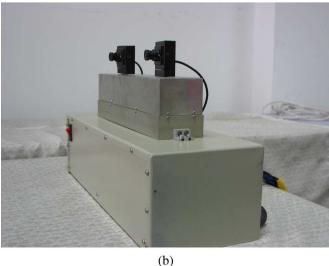

Fig. 7. Experiment system. (a) Principle scheme. (b) Actual system.

Fig. 8. Scene of calibration for initial optical directions.

256 From (5), the relative error  $dx_h/z_h$  is deduced as follows:

$$\frac{dx_h}{z_h} = \frac{dz_h}{z_h} \tan \alpha_1 - \frac{dD}{2z_h} + \frac{d\alpha_1}{(\cos \alpha_1)^2}.$$
 (19)

257 In (19), the terms containing  $dD/z_h$  and  $d\alpha_1$  are so small 258 that they can be neglected. It is certain that  $dx_h/z_h$  is smaller 259 than  $dz_h/z_h$  since  $\tan\alpha_1<1$ .

From (9) to (11), the relative error  $dy_h/z_h$  is deduced as 260 follows:

$$\begin{split} \frac{dy_h}{z_h} &= \frac{1}{2} \frac{v_{1d}}{u_{1d}} \left[ \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} \frac{dz_h}{z_h} \right. \\ &\quad \left. + \frac{\cos \alpha_2 d\alpha_1 - \cos(\alpha_1 - \alpha_2) \cos \alpha_1 d\alpha_2}{(\cos \alpha_1)^2} \right] \\ &\quad \left. + \frac{1}{2} \frac{v_{2d}}{u_{2d}} \left[ \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_2} \frac{dz_h}{z_h} \right. \\ &\quad \left. + \frac{\cos(\alpha_1 - \alpha_2) \cos \alpha_2 d\alpha_1 - \cos \alpha_1 d\alpha_2}{(\cos \alpha_2)^2} \right] \\ &\quad \left. + \frac{1}{2} \frac{dv_{1d}}{u_{1d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} + \frac{1}{2} \frac{dv_{2d}}{u_{2d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_2} \right. \\ &\quad \left. - \frac{1}{2} \frac{v_{1d} du_{1d}}{u_{1d}^2} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} - \frac{1}{2} \frac{v_{2d} du_{2d}}{u_{2d}^2} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_2} \right. \end{split}$$

where  $du_{1d}$ ,  $dv_{1d}$ ,  $du_{2d}$ , and  $dv_{2d}$  are the errors in  $u_{1d}$ ,  $v_{1d}$ , 262  $u_{2d}$ , and  $v_{2d}$ , respectively.

The terms such as  $[\cos\alpha_2 d\alpha_1 - \cos(\alpha_1 - \alpha_2)\cos\alpha_1 d\alpha_2]/264$   $(\cos\alpha_1)^2$  and  $[\cos(\alpha_1 - \alpha_2)\cos\alpha_2 d\alpha_1 - \cos\alpha_1 d\alpha_2]/(\cos\alpha_2)^2$  265 in (20) are negligible when the angles  $\alpha_1$  and  $\alpha_2$  are small 266 enough. Terms with  $du_{1d}$  and  $du_{2d}$  are negligible after the 267 initial angles of the optical axes are calibrated. Then, (20) can 268 be rewritten as follows:

$$\frac{dy_h}{z_h} \approx \frac{1}{2} \left[ \frac{v_{1d}}{u_{1d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} + \frac{v_{2d}}{u_{2d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_2} \right] \frac{dz_h}{z_h} + \frac{1}{2} \left[ \frac{dv_{1d}}{u_{1d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} + \frac{dv_{2d}}{u_{2d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_2} \right]. \tag{21}$$

It is found from (21) that  $dy_h/z_h$  is smaller than  $dz_h/z_h$  since 270  $\sin(\alpha_1 - \alpha_2)/\cos\alpha_1 \ll 1$  and  $\sin(\alpha_1 - \alpha_2)/\cos\alpha_2 \ll 1$  when 271  $v_{1d}$  and  $v_{2d}$  are accurate,  $u_{1d}$  and  $u_{2d}$  are not very small, and  $\alpha_1$  272 and  $\alpha_2$  are small enough. In the case of very small  $u_{1d}$  and  $u_{2d}$ , 273 the error  $dy_h/z_h$  will be large. An alternative method to solve 274 this problem is given as follows. When  $y_{c1}$  is calculated with 275 (9),  $u_{1d}$  and  $v_{1d}$  are generated in the condition  $\alpha_2 = 0$ . While 276  $y_{c2}$  is calculated with (10),  $u_{2d}$  and  $v_{2d}$  are generated in the 277 condition  $\alpha_1 = 0$ . In the case that there are large errors in  $v_{1d}$  278 and  $v_{2d}$ , the error  $dy_h/z_h$  is apparent since it is proportional 279 to  $dv_{1d}$  and  $dv_{2d}$ . In addition,  $k_x$  and  $k_y$  are very close for 280 most cameras. Generally, the value of  $k_y/k_x$  is close to 1 with 281 an error of less than 2%. For example, when  $\alpha_1 = \pi/6$ ,  $\alpha_2 = 282$  $\pi/12$ ,  $u_{1d} = 40$ ,  $v_{1d} = 50$ ,  $u_{2d} = 45$ ,  $v_{2d} = 60$ ,  $dz_h/z_h = 2\%$ , 283  $dv_{1d} = 50$ , and  $dv_{2d} = 50$ , the relative error  $dy_h/z_h$  is not more 284 than 1.1%. It means that the relative error  $dy_h/z_h$  is not very 285 sensitive to the cameras' intrinsic parameters.

From (16) and (18), it should be noted that the term dD/D 289 is a small constant since  $D\gg dD$ . Thus, the relative errors in 290  $\alpha_1$  and  $\alpha_2$  may be the main source for the relative error in  $z_h$ . 291

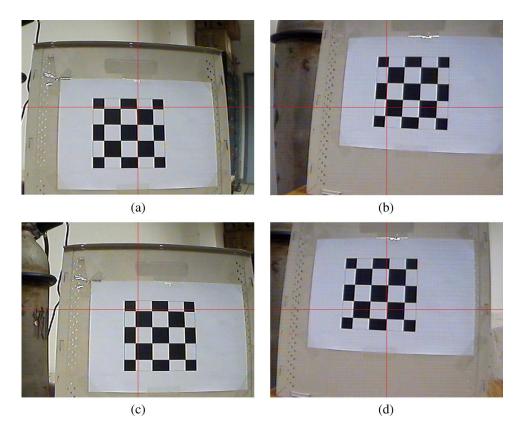

Fig. 9. Some images of the object to be measured in experiments. (a) Image of chessboard in  $C_{a1}$  and (b) image in  $C_{a2}$  at the first step. (c) Image in  $C_{a1}$  and (d) image in  $C_{a2}$  at the second step.

292 The initial yawing angles of the cameras are assumed to be 293 zero, and the optical axes are assumed to be parallel. In fact, 294 the actual initial yawing angles will not be zero. As mentioned 295 in Section II-B, the optical axes of two cameras are just almost 296 parallel in the initial state. Obviously, there exist system errors 297 denoted as  $\alpha_{e1}$  and  $\alpha_{e2}$  for  $\alpha_1$  and  $\alpha_2$ , respectively, in the initial 298 state. The calibration of the initial directions of optical axes is 299 to find the values of  $\alpha_{e1}$  and  $\alpha_{e2}$ .

Taking  $\alpha_{e1}$  and  $\alpha_{e2}$  into account, (4) is rewritten as follows:

$$\tan(\alpha_1 + \alpha_{e1}) + \tan(\alpha_2 + \alpha_{e2}) = D/z_h.$$
 (22)

With the expansion and simplification of (22), the following 302 equation is derived:

$$a_1xy + a_2x + a_3y + a_4 = 0 (23)$$

303 where

$$\begin{cases} x = \tan \alpha_{e1} \\ y = \tan \alpha_{e2} \\ a_1 = \tan \alpha_1 + \tan \alpha_2 + \tan \alpha_1 \tan \alpha_2 D/z_h \\ a_2 = \tan \alpha_1 \tan \alpha_2 - \tan \alpha_1 D/z_h - 1 \\ a_3 = \tan \alpha_1 \tan \alpha_2 - \tan \alpha_2 D/z_h - 1 \\ a_4 = D/z_h - \tan \alpha_1 - \tan \alpha_2. \end{cases}$$
(24)

Formula (23) is a nonlinear equation for parameters x and y. 305 In the calibration, a block is placed in front of the two cameras; 306 the distance from the block to the midpoint of the two cameras 307 can be measured. The cameras are yawed to have  $\alpha_1$  and  $\alpha_2$  308 as described in Section II-C. Changing the block's position a

number of times, a series of nonlinear equations as (23) are 309 formed.

Let 311

$$f_i(x,y) = a_{1i}xy + a_{2i}x + a_{3i}y + a_{4i}$$
 (25)

where  $a_{1i}$  to  $a_{4i}$  are the coefficients  $a_1$  to  $a_4$  computed from 312 (24) at the *i*th sampling of calibrating data.

Then, an objective function F(x,y) can be defined as 314 follows:

$$F(x,y) = \sum_{i=1}^{n} f_i^2(x,y)$$
 (26)

where n is the sampling times, i.e., the groups of data formed 316 for calibration.

Now, the solution of the nonlinear (23) is converted to an 318 optimization problem to find the optimal parameters x and y to 319 make F(x,y) be minimum. As it is known, the quasi-Newton 320 method is efficient to solve this problem.

After the above calibration, the parameters  $u_{10}$  and  $u_{20}$  in (9) 322 and (10) can be evaluated to the image horizontal coordinates 323 of the image center. 324

### VI. EXPERIMENTS AND RESULTS

325

An experiment system was designed as shown in Fig. 7, in 326 which Fig. 7(a) was its principle scheme, and Fig. 7(b) was the 327 actual system. It consisted of two miniature cameras that could 328 AQ1 be simultaneously yawed in opposite directions. A step motor 329

330 was employed to drive the rotation of cameras through the belt 331 and gears. The system was adjusted so that the optical axes of 332 the two cameras were almost parallel initially. The distance be-333 tween the two cameras was 150 mm. The rotational resolution 334 of the two cameras was  $2\pi/25\,600 = 2.45 \times 10^{-4}$  rad.

335 A series of measurement experiments were conducted with 336 the visual system, as shown in Fig. 7(b). First, the initial 337 directions of the optical axes of two cameras were calibrated 338 with the method described in Section V. A scene of optical 339 initial direction calibration was given in Fig. 8. The results were 340  $\alpha_{e1}=0.0578$  rad and  $\alpha_{e2}=-0.0254$  rad. Then, the measure-341 ment method, as described in Section II-C, was employed in the 342 visual measuring experiments.

#### 343 A. Chessboard Measurement

An experiment to measure the blocks in a chessboard was 345 designed to test the effectiveness of the proposed method and 346 system. In the visual measuring experiment, the cameras were 347 yawed to make the horizontal imaging coordinates of the fea-348 ture point be equal to those of the image plane centers of the two 349 cameras separately for each point to be measured in Cartesian 350 space. As described in Section II-C, the cameras were yawed in 351 two steps, and two yawing angles  $\alpha_1$  and  $\alpha_2$  were generated. In 352 Fig. 9, the images captured by the two cameras for the measure 353 of a point were given. Fig. 9(a) was an image of chessboard 354 in  $C_{a1}$ , Fig. 9(b) an image in  $C_{a2}$  at the first step, Fig. 9(c) 355 an image in  $C_{a1}$ , and Fig. 9(d) an image in  $C_{a2}$  at the second 356 step. The image size was  $640 \times 480$  in pixel, and its center was 357 [320, 240]. In the experiment,  $u_{10}$  and  $u_{20}$  were evaluated to 358 be 320;  $v_{10}$  and  $v_{20}$  were evaluated to be 240. It can be seen 359 that the images have large distortions, and the optical axes of 360 the two cameras might not be parallel.

14	20.4779	50.8963	532.7708
15	50.6692	53.0560	528.3036
16	79.5523	52.1520	522.6241

The image offset coordinates from the image center and the 361 yawing angles for cross points in the chessboard were listed 362 in Table I. It can be seen that the offset coordinates  $u_{1d}$  and 363  $u_{2d}$  of points 2, 6, 10, and 14 were very small. As analyzed 364 at the end of Section IV, the calculation of  $y_{c1}$  and  $y_{c2}$  would 365 introduce large errors. To deal with this problem, several data 366 were captured for the four points above, that is,  $u_{1d}$  and  $v_{1d}$  367 were generated in the condition  $\alpha_2=0$ , and  $u_{2d}$  and  $v_{2d}$  were 368 generated in the condition  $\alpha_1=0$ .

The coordinates  $z_h$  and  $x_h$  in frame H were computed using 370 (4) and (5) according to  $\alpha_1$  and  $\alpha_2$  modified with  $\alpha_{e1}$  and  $\alpha_{e2}$ . 371 With the image coordinates and yawing angles listed in Table I, 372  $y_{c1}$  and  $y_{c2}$  were calculated via (9) and (10), except for points 2, 373 6, 10, and 14. It should be noted that the term  $\alpha_1 - \alpha_2$  in (9) and 374 (10) denoted the relative rotation angle. Thus,  $\alpha_1$  and  $\alpha_2$  in the 375 numerators of (9) and (10) did not need to be modified with  $\alpha_{e1}$  376 and  $\alpha_{e2}$ .  $\alpha_1$  in the denominator of (9) and  $\alpha_2$  in the denominator 377 of (10) were the yawing angles relative to the axis  $Z_h$ , and they 378 need to be modified with  $\alpha_{e1}$  and  $\alpha_{e2}$ . For points 2, 6, 10, and 379 14,  $y_{c1}$  was calculated via (9) with the image offset coordinates 380 in Table II,  $\alpha_1$  in Table I, and  $\alpha_2 = 0$ .  $y_{c2}$  was calculated 381 for these points via (10) with the image offset coordinates in 382 Table II,  $\alpha_2$  in Table I, and  $\alpha_1 = 0$ . The average value of  $y_{c1}$  and 383  $y_{c2}$  was taken as the coordinate  $y_h$ . The experimental results to 384 measure a chessboard were listed in Table III. The data were 385 the 3-D positions of the cross points on the chessboard in the 386 vision system frame H. They were also shown in Fig. 10(a) 387 for convenience of evaluation. The actual width and height for 388 each block in the chessboard were both 30 mm. The measured 389 width and height computed from the distances between any two 390 adjacent cross points in the pattern were listed in Table IV and 391 also shown in Fig. 10(b). Its mean is 30.3 mm, and the standard 392 deviation was 0.677 mm. In addition, Fig. 10(b) also displayed 393 the difference of  $y_{c1}$  and  $y_{c2}$  computed from (9) and (10). It 394 can be found that the differences were stable. Therefore, the 395 differences can be considered as the offsets resulting from the 396 nonparallel axes of the two cameras, in respect of an object in 397 some depth  $Z_h$ .

From Fig. 10 and Tables III and IV, it can be found that 399 the measuring accuracy with the proposed visual system and 400

401 method was satisfactory even if the camera lens had large 402 distortion.

## 403 B. Comparison With Stereovision

404 To compare the proposed method with the traditional 405 stereovision method, the two cameras were well calibrated 406 with Zhang's calibration method [6]. The intrinsic parameters 407 of the cameras were as follows:  $k_{x1}=834.82771,\ k_{y1}=408.815.41740,\ u_{10}=303.8,\ v_{10}=306.3,\ k_{x2}=850.45548,$  409  $k_{y2}=833.29453,\ u_{20}=345.1,\$ and  $v_{20}=197.3.$  The 410 distortion factors of the lens in the radial direction were 411  $k_{c1}=-0.38741$  and  $k_{c2}=-0.30938$  for cameras  $C_{a1}$  and 412  $C_{a2}$  separately. The extrinsic parameter matrix  $^{c1}T_{c2}$ , i.e., the

pose of camera  $C_{a2}$  relative to camera  $C_{a1}$ , was well calibrated 413 as given in (27) when the two cameras were at the initial 414 positions, i.e., 415

$${}^{c1}T_{c2} = \begin{bmatrix} 0.9995 & -0.0236 & -0.0222 & -150.9556 \\ 0.0234 & 0.9997 & -0.0091 & -5.1851 \\ 0.0224 & 0.0086 & 0.9997 & 2.2226 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$
(27)

The experiment scene was similar to that of the initial optical 417 direction calibration, as given in Fig. 8. The intersection be- 418 tween the two black blocks on a target, as shown in Fig. 8, was 419 selected as the point P to be measured. When the target was 420 placed at a position in front of the visual system, the two cam- 421 eras were yawed to initial directions and captured the target's 422 images. The Cartesian space position of point P in the frame 423

456

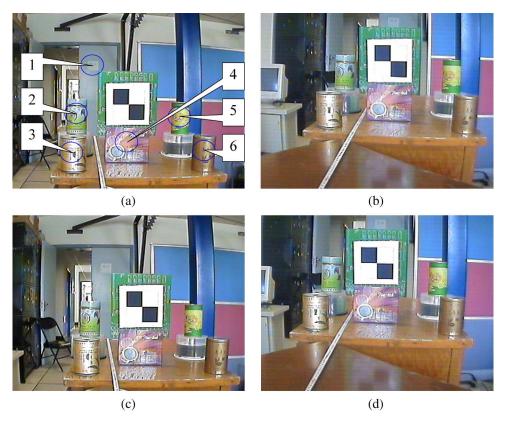

Fig. 12. Images of the objects in experiments. (a) Image in  $C_{a1}$  and (b) image in  $C_{a2}$  at the first step. (c) Image in  $C_{a1}$  and (d) image in  $C_{a2}$  at the second step.

424 of camera  $C_{a1}$  was calculated with the traditional stereovision 425 method. The coordinates of point P in frame H were obtained 426 via transformations including the rotation with  $\alpha_{e1}$  around axis 427  $y_{c1}$  and the translation with D/2 along axis  $x_{c1}$ . Then, the two 428 cameras were yawed with a tracking algorithm in two steps to 429 generate  $\alpha_1$  and  $\alpha_2$ , and the coordinates of point P in frame 430 H were computed with the proposed method as described in 431 Section II-C. The procedure above was repeated while the target 432 was placed at different positions in front of the visual system, 433 and six groups of visual measuring results were formed as given 434 in Tables V and VI. They are also displayed in Fig. 11 for 435 assessing convenience.

The results from the stereovision method were computed 437 using the intrinsic and extrinsic parameters of the two cam-438 eras, as given above in this section. The lens distortion in 439 the radial direction was also taken into account. The results 440 from the proposed method did not use the parameters such 441 as  $k_{x1}$ ,  $k_{y1}$ ,  $k_{x2}$ , and  $k_{y2}$ , and the distortion factors  $k_{c1}$  and 442  $k_{c2}$ . The y-coordinates of the measured positions with the 443 proposed method in Table V were computed in the condition 444 that  $u_{10}=320$ ,  $v_{10}=306.3$ ,  $u_{20}=320$ , and  $v_{20}=197.3$ . The 445 y-coordinates in Table VI were computed with the proposed 446 method in the condition that  $u_{10}=320$ ,  $v_{10}=240$ ,  $u_{20}=447\ 320$ , and  $v_{20}=240$ . In other words, the results in Table VI 448 were calculated in the case that the intrinsic parameters of the 449 cameras were supposed to be not available.

450 From Fig. 11 and Tables V and VI, it can be found that 451 the measuring accuracy with the proposed visual system and 452 method was very close to that with the stereovision method, 453 even if the cameras' intrinsic parameters were not employed,

and the large distortion in the camera lens was not taken into 454 account in the proposed method.

## C. Relative Positioning

To verify the effectiveness of the relative positioning method 457 for multiple objects, an experiment was conducted. A board 458 target with two black blocks, as shown in Fig. 8, was selected 459 as the main object, which was surrounded by other objects. The 460 intersection of the two blocks was selected as the feature point. 461 As described in Section II-C, the cameras were yawed with a 462 tracking algorithm in two steps. In the first step, the cameras 463 were yawed to make the feature point be at the horizontal center 464 in the image of camera  $C_{a1}$ . In the second step, the cameras 465 were yawed to make the feature point be at the horizontal center 466 in the image of camera  $C_{a2}$ .  $\alpha_1$  and  $\alpha_2$  were generated as 467  $\alpha_1 = 0.08$  and  $\alpha_2 = 0.0349$ . Each camera captured an image 468 at the end of each step. Four frames of images were captured at 469 the two measuring positions for the two cameras, as shown in 470 Fig. 12.

The six objects to be measured were represented by their 472 image centers. The image coordinates  $u_{11k}$ ,  $u_{12k}$ ,  $u_{21k}$ , and 473  $u_{22k}$ ,  $k=1,2,\ldots,6$ , for the six objects extracted from the four 474 images captured by the two cameras in the two steps, were 475 listed in Table VII. Applying (12) to the image coordinates of 476 the six objects, we had the areas that the objects belonged to. In 477 other words, the approximate positions of the objects relative to 478 the main object were obtained, as listed in Table VII. It is easy 479 to check the correctness of the relative positioning results via 480 comparison to their actual positions.

482 In addition, experiments with the proposed visual system 483 and method, in Sections VI-A and B, also gave evidence that 484 the measuring precision would be heavily influenced by the 485 directions of the optical axes of the two cameras in the initial 486 state. Therefore, the calibration of the initial directions of the 487 optical axes of the two cameras is important to ensure the 488 precision in practical visual measurements.

#### VII. CONCLUSION

490 A new active visual system is developed, which consists 491 of two cameras and a two-DOF mechanical platform. Two 492 cameras are mounted on the platform, which can pitch and yaw. 493 The two cameras can be simultaneously adjusted in opposite di-494 rections. With pitching and yawing of the platform, and relative 495 yawing of the cameras, the object's images can be adjusted to 496 the center areas of the image planes of the two cameras. Then, 497 the position of the object is determined with the geometrical 498 information of the visual system. Furthermore, a more general 499 visual model is proposed. It consists of two cameras that can 500 yaw in opposite directions. In two steps, the object's images 501 are adjusted to the center areas of the image planes of the two 502 cameras separately. The position of an object can be calculated 503 with the yawing angles and the image coordinates of the object 504 in the two steps.

The visual system proposed in this paper is based on bionic 506 vision and is insensitive to the intrinsic parameters of the 507 camera. Experiment results showed that the measuring accuracy 508 with the proposed visual system and method was very close 509 to that with a stereovision method, even if the actual intrinsic 510 parameters of the cameras were not available, and large dis-511 tortion in the camera lens was not taken into account in the 512 proposed method. Low efficiency in measuring multiple objects 513 is its main limitation. However, the cases with the tracking or 514 measuring of multiple objects are uncommon in a visual control 515 system.

Future work will be focused on its applications such as 517 navigation, object tracking, approaching, and grasping for hu-518 manoid robots.

# A New Active Visual System for Humanoid Robots

De Xu, Member, IEEE, You Fu Li, Senior Member, IEEE, Min Tan, and Yang Shen

Abstract—In this paper, a new active visual system is developed, 4 which is based on bionic vision and is insensitive to the property 5 of the cameras. The system consists of a mechanical platform 6 and two cameras. The mechanical platform has two degrees of 7 freedom of motion in pitch and yaw, which is equivalent to the 8 neck of a humanoid robot. The cameras are mounted on the 9 platform. The directions of the optical axes of the two cameras 10 can be simultaneously adjusted in opposite directions. With these 11 motions, the object's images can be located at the centers of the 12 image planes of the two cameras. The object's position is deter-13 mined with the geometry information of the visual system. A more 14 general model for active visual positioning using two cameras 15 without a neck is also investigated. The position of an object can 16 be computed via the active motions. The presented model is less 17 sensitive to the intrinsic parameters of cameras, which promises 18 more flexibility in many applications such as visual tracking with 19 changeable focusing. Experimental results verify the effectiveness 20 of the proposed methods.

21 *Index Terms*—Active vision, bionic vision, humanoid robot, 22 positioning, visual system.

#### I. Introduction

24 THE PINHOLE model for cameras has been widely used in robot visual systems [1]. Generally, the parameters in 26 the camera model need to be calibrated to perform visual mea-27 surement or control. The inherent parameters of a camera, such 28 as the focus length, the principal point, and the magnification 29 coefficients from the imaging plane coordinates to the image 30 coordinates, are referred to as intrinsic parameters. The external 31 parameters such as the relative positions and orientations of 32 cameras are the extrinsic parameters. In many applications such 33 as visual positioning [2], [3] and motion estimation [4], only 34 the intrinsic parameters are of concern. On the other hand, the 35 intrinsic and extrinsic parameters are important in applications 36 with stereovision [5]. Up to now, the calibration for intrinsic 37 parameters of a camera [5] has been well studied including the 38 use of a special planar pattern [6], [7]. Although the methods 39 are effective, their calibrating process is, in general, tedious and 40 prone to errors.

Manuscript received March 5, 2007; revised July 5, 2007. To reduce the influence of the errors in camera calibration 41 on visual control, some researchers developed the image-based 42 visual servoing (IBVS) [1], [8] and hybrid visual servoing 43 methods [9]. The camera's parameters are not separately es- 44 timated in IBVS, but included in the estimation of the image 45 Jacobian matrix. With the camera parameters in the feedback 46 loop of the image features, the influence of errors in camera 47 calibration is reduced, but still exists.

Self-calibrating methods have been studied to eliminate the 49 need for special patterns and to increase the adaptability of 50 the visual system. One category of such calibration is based 51 on special motions of the camera [10]. Another is based on 52 the environment information such as parallel lines [11]-[13]. 53 Recently, attention has focused on uncalibrated visual servoing 54 (UCVS). In fact, the cameras in some UCVS systems are self- 55 calibrated [14]. The methods in some UCVS systems belong 56 to IBVS since cameras' parameters are not individually esti- 57 mated, but combined into the estimation of the image Jacobian 58 matrix [15]. Some researchers pursue the visual control without 59 camera parameters [16]-[18]. For instance, Shen et al. [16] 60 limited the workspace of the end-effector on a plane that is 61 vertical to the optical axis of the camera to eliminate the camera 62 parameters in the image Jacobian matrix. A visual control 63 method based on the epipolar line and the cross ratio invariance 64 was developed with two uncalibrated cameras in [18]. It did 65 not use camera parameters, and the working space of the end- 66 effector was in 3-D Cartesian space. However, this method was 67 limited to approaching task.

The results of traditional visual measurements are dependent 69 much on cameras' parameters, particularly the intrinsic param-70 eters. In general, the focus of a camera is fixed, which heavily 71 limits its flexibility in practical applications such as visual 72 tracking. In addition, a camera needs to be calibrated before it 73 is to be used for a new task. Obviously, the visual measurement 74 and control methods that are insensitive to camera intrinsic 75 parameters would be much more flexible and convenient to use 76 than traditional ones.

The motivation of this paper is to develop a new visual 78 system that is insensitive to the property of the cameras. An 79 active visual system as well as its positioning method is de- 80 signed to conduct visual measurement in the center areas of the 81 cameras, which is insensitive to the intrinsic parameters. With 82 the geometry information of our visual system, the position of 83 an object can be determined even if the intrinsic parameters 84 of the cameras are not available. The rest of this paper is 85 organized as follows. The bionic visual models are introduced 86 in Section II. One model is for the humanoid robot with a head 87 of two degrees of freedom (DOFs). Another is a general model 88 for any mobile robots. In Section III, the relative positioning for 89 multiple objects is discussed. Section IV investigates the errors 90

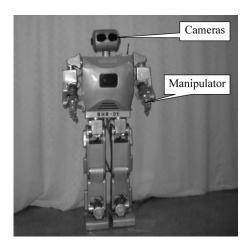

Fig. 1. Structure of a humanoid robot.

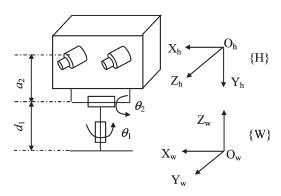

Fig. 2. Sketch of the neck and the head.

91 for the two proposed models. The calibration method for the 92 initial directions of the optical axes of the cameras is provided 93 in Section V. The experimental results are given in Section VI. 94 Finally, this paper is concluded in Section VII.

#### II. BIONIC VISUAL MODEL

#### 96 A. Visual System for a Humanoid Robot

95

A humanoid robot has a typical configuration of the visual system as follows [19]. There are two cameras mounted on the head of the robot, which serve as the eyes. An eye-to-hand too system is formed with these two cameras and a manipulator. The head has two DOFs: yaw and pitch [20]. The cameras and DOFs, the head can be taken as an eye-in-hand system. With the two DOFs, the head can work as an active vision system (Fig. 1). The sketch of the neck and the head of a humanoid robot is given in Fig. 2. The first joint is responsible for yawing, and the second one for pitching. The world frame W for the head to sassigned at the connect point of the neck and the body. The head frame H is assigned at the midpoint of the two cameras.

#### 109 B. Bionic Visual Model for a Humanoid Robot

The two cameras can simultaneously yaw in opposite di-111 rections to stare at an object. In the initial state of the two 112 cameras, they are well mounted so that their optical axes are 113 almost parallel. Therefore, the line connecting the two cameras 114 is on the plane formed by the two optical axes. The following

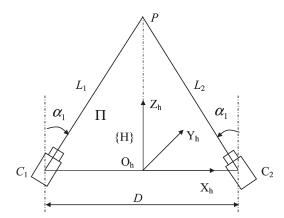

Fig. 3. Principle of visual positioning.

symbols are defined to describe the cameras (see also Fig. 3). 115  $L_1$  denotes the optical axis of a camera  $C_{a1}$ .  $C_1$  is its optical 116 principal point.  $L_2$  and  $C_2$  indicate the optical axis and the 117 optical principal point, respectively, of another camera  $C_{a2}$ .  $\Pi$  118 denotes the plane formed by  $L_1$  and  $L_2$ . The position of a point 119 P is expressed as  $[x_h,y_h,z_h]$  in frame H, and  $[x_w,y_w,z_w]$  in 120 frame W.

For a point P, it can be adjusted to be on the plane  $\Pi$  122 with the change in  $\theta_2$ . Then, it can be on the perpendicular 123 bisector of line  $C_1C_2$  on the plane  $\Pi$  with the adjustment of 124  $\theta_1$ . With simultaneous yawing in opposite directions for the 125 two cameras, the images of point P can be placed at the center 126 positions of the image planes of the two cameras.

The transformation matrix from frame W to H is given in (1) 128 according to the Denavit–Hartenberg (D-H) parameters model, 129 where  $d_1$  and  $a_2$  are the D-H parameters of the neck's joints.  $\theta_1$  130 and  $\theta_2$  are the joint angles of the two joints.

$${}^{w}T_{h} = \begin{bmatrix} \cos\theta_{1} & -\sin\theta_{1}\sin\theta_{2} & -\sin\theta_{1}\cos\theta_{2} & a_{2}\sin\theta_{1}\sin\theta_{2} \\ \sin\theta_{1} & \cos\theta_{1}\sin\theta_{2} & \cos\theta_{1}\cos\theta_{2} & -a_{2}\cos\theta_{1}\sin\theta_{2} \\ 0 & -\cos\theta_{2} & \sin\theta_{2} & a_{2}\cos\theta_{2} + d_{1} \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

$$(1)$$

Assume that the yawing angles of the two cameras are equal 132 to  $\alpha_1$ . It is known from Fig. 1 that the coordinates of point P in 133 frame H are zero in the axes  $X_h$  and  $Y_h$ . The coordinate in the 134 axis  $Z_h$  is

$$z_h = D/(2\tan\alpha_1) \tag{2}$$

140

where D is the distance between the optical principal points of 136 the two cameras, and  $\alpha_1$  is the yawing angle.

The position of point P in frame W can be calculated with 138 (3) according to (1) and (2), i.e.,

$$\begin{bmatrix} x_w \\ y_w \\ z_w \\ 1 \end{bmatrix} = {}^wT_h \begin{bmatrix} x_h \\ y_h \\ z_h \\ 1 \end{bmatrix} = \begin{bmatrix} -z_h \sin \theta_1 \cos \theta_2 + a_2 \sin \theta_1 \sin \theta_2 \\ z_h \cos \theta_1 \cos \theta_2 - a_2 \cos \theta_1 \sin \theta_2 \\ z_h \sin \theta_2 + a_2 \cos \theta_2 + d_1 \\ 1 \end{bmatrix}. \tag{3}$$

# C. General Bionic Visual Model

The general bionic visual model is designed for the robots 141 without the neck. It consists of two cameras simultaneously 142

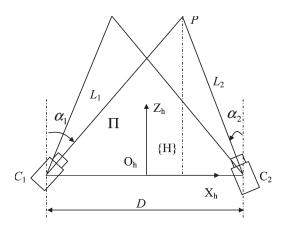

Fig. 4. Principle of visual positioning with the general model.

143 yawing in opposite direction. In such a case, it is impossible 144 to place the images of a point P at the center positions of the 145 image planes of the two cameras at the same time. However, 146 its horizontal imaging coordinates can be equal to those of 147 the image plane centers of the two cameras separately. The 148 cameras are simultaneously yawed in two steps, in which the 149 coordinates of the image plane centers are taken as the desired 150 values. In the first step, the horizontal imaging coordinate of 151 point P in camera  $C_{a1}$  is adjusted to the desired value, and the 152 image coordinates of point P in camera  $C_{a2}$  are recorded. In 153 the second step, the horizontal imaging coordinate of point P 154 in camera  $C_{a2}$  is adjusted to the desired value, and the image 155 coordinates of point P in camera  $C_{a1}$  are recorded. The yawing 156 angles in the two steps are recorded as  $\alpha_1$  and  $\alpha_2$ . In the  $X_h Z_h$  157 plane, the geometric relation is shown in Fig. 4.

158 From the geometric relation in Fig. 4,  $z_h$  and  $x_h$  are com-159 puted as follows:

$$z_h = D/(\tan \alpha_1 + \tan \alpha_2) \tag{4}$$

$$x_h = z_h \tan \alpha_1 - D/2 \tag{5}$$

160 where  $\alpha_1$  is the yawing angle in the first step, and  $\alpha_2$  is the 161 yawing angle in the second step.

For camera  $C_{a1}$ , the relation between the coordinates in im-163 age and Cartesian space can be expressed as follows according 164 to the pinhole model with four intrinsic parameters:

$$\begin{cases} u_{11} - u_{10} = k_{x1} \frac{x_{c1}}{z_{c1}} \\ v_{11} - v_{10} = k_{y1} \frac{y_{c1}}{z_{c1}} \end{cases}$$
 (6)

165 where  $[u_{11},v_{11}]$  are the image coordinates of point P in camera 166  $C_{a1}$  in the second step.  $[u_{10},v_{10}]$  are the image coordinates of 167 the optical principal point, and  $u_{10}$  is used as the desired image 168 coordinate in the first step.  $[x_{c1},y_{c1},z_{c1}]$  are the Cartesian 169 coordinates of point P in the frame of camera  $C_{a1}$  in the second 170 step.  $k_{x1}$  and  $k_{y1}$  are the scale factors from imaging plane 171 coordinates to the image coordinates.

72  $y_{c1}$  can be deduced from (6) with the elimination of  $z_{c1}$ , i.e.,

$$y_{c1} = \frac{v_{11} - v_{10}}{u_{11} - u_{10}} \frac{k_{x1}}{k_{y1}} x_{c1} \approx \frac{v_{1d}}{u_{1d}} x_{c1}$$
 (7)

173 where  $u_{1d} = u_{11} - u_{10}$  and  $v_{1d} = v_{11} - v_{10}$ .

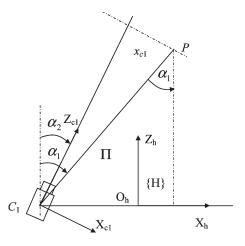

Fig. 5. Geometric relation for a camera.

From the geometric relation as shown in Fig. 5,  $x_{c1}$  can be 174 expressed with  $z_h$ , i.e.,

$$x_{c1} = \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} z_h \tag{8}$$

where  $\alpha_1$  and  $\alpha_2$  are same as described in (4).

Applying (8) to (7), 
$$y_{c1}$$
 can be obtained, i.e.,

$$y_{c1} \approx \frac{v_{1d}}{u_{1d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} z_h. \tag{9}$$

Similarly,  $y_{c2}$  can be obtained as follows for camera  $C_{a2}$ :

$$y_{c2} \approx \frac{v_{2d}}{u_{2d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_2} z_h \tag{10}$$

where  $u_{2d}=u_{21}-u_{20}$  and  $v_{2d}=v_{21}-v_{20}$ .  $[u_{21},v_{21}]$  are the 179 image coordinates of point P in camera  $C_{a2}$  in the first step. 180  $[u_{20},v_{20}]$  are the image coordinates of the optical principal 181 point of camera  $C_{a2}$ , and  $u_{20}$  is used as the desired image 182 coordinate of point P in the second step.  $y_{c2}$  is the Cartesian 183 coordinate of point P on the  $Y_{c2}$ -axis in the frame of camera 184  $C_{a2}$  in the first step.

The average of  $y_{c1}$  and  $y_{c2}$  is taken as the coordinate  $y_h$ , i.e., 186

$$y_h = (y_{c1} + y_{c2})/2.$$
 (11)

The position of a point P in world frame W is easy to be 187 obtained for the robot with a neck of two DOFs via coordinate 188 transformation after its position in frame H is obtained [see also 189 (3)]. This is very helpful for a robot to track an object in a large 190 range.

#### III. RELATIVE POSITIONING FOR MULTIPLE OBJECTS 192

Suppose that there are multiple objects in the common view 193 field of two cameras. One object is selected as reference, and it 194 is measured using the method in Section II-C. The symbols  $L_{11}$  195 and  $L_{12}$  denote optical lines in two steps for camera  $C_{a1}$ , and 196 the symbols  $L_{21}$  and  $L_{22}$  for camera  $C_{a2}$ . The view fields can 197 be divided into 12 areas from  $S_1$  to  $S_{12}$ , as shown in Fig. 6, with 198 lines  $L_{11}$ ,  $L_{12}$ ,  $L_{21}$ , and  $L_{22}$ , and the  $Z_h$ -axis. It is found that 199 the areas  $S_1$  and  $S_2$  are distinguished with the  $Z_h$ -axis, so are 200

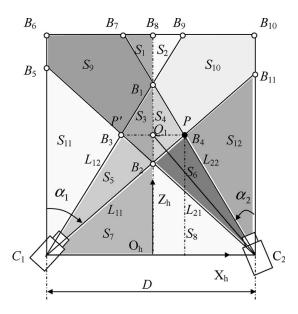

Fig. 6. Areas division in relative positioning.

201 the areas  $S_3$  and  $S_4$ , and  $S_7$  and  $S_8$ . The other areas are divided 202 by optical lines  $L_{11}$ ,  $L_{12}$ ,  $L_{21}$ , and  $L_{22}$ .

Four frames of images are captured at the two measuring 204 positions with yawing angles  $\alpha_1$  and  $\alpha_2$  for the two cameras. 205 The image coordinates are indicated with  $[u_{ijk}, v_{ijk}]$  for object 206 k in the image j of camera i. The area in which object k 207 locates can be determined with the image coordinates of object 208 k and the optical principal points, i.e.,  $[u_{ijk}, v_{ijk}]$  and  $[u_{i0}, v_{i0}]$ , 209 i = 1, 2, j = 1, 2. The division can be concluded as given in 210 (12) from Fig. 6, i.e.,

$$S \in \begin{cases} S_{1}, & \text{if } u_{12k} < u_{10}, \ u_{22k} > u_{20}, \ |u_{12kd}| > |u_{22kd}| \\ S_{2}, & \text{if } u_{12k} < u_{10}, \ u_{22k} > u_{20}, \ |u_{12kd}| < |u_{22kd}| \\ S_{3}, & \text{if } u_{11k} < u_{10}, \ u_{12k} > u_{10}, \ u_{21k} > u_{20}, \\ & u_{22k} < u_{20}, |u_{11kd}| > |u_{21kd}| \\ S_{4}, & \text{if } u_{11k} < u_{10}, \ u_{12k} > u_{10}, \ u_{21k} > u_{20}, \\ & u_{22k} < u_{20}, |u_{11kd}| < |u_{21kd}| \\ S_{5}, & \text{if } u_{11k} < u_{10}, \ u_{12k} > u_{10}, \ u_{21k} < u_{20} \\ S_{6}, & \text{if } u_{11k} > u_{10}, \ u_{21k} > u_{20}, \ u_{22k} < u_{20} \\ S_{7}, & \text{if } u_{11k} > u_{10}, \ u_{21k} < u_{20}, \ |u_{11kd}| < |u_{21kd}| \\ S_{8}, & \text{if } u_{11k} > u_{10}, \ u_{21k} < u_{20}, \ |u_{11kd}| > |u_{21kd}| \\ S_{9}, & \text{if } u_{12k} < u_{10}, \ u_{21k} > u_{20}, \ u_{22k} < u_{20} \\ S_{10}, & \text{if } u_{11k} < u_{10}, \ u_{12k} > u_{10}, \ u_{22k} > u_{20} \\ S_{11}, & \text{if } u_{12k} < u_{10}, \ u_{21k} < u_{20} \\ S_{12}, & \text{if } u_{11k} > u_{10}, \ u_{22k} > u_{20} \end{cases}$$

$$(12)$$

211 where S is the area in which the object k locates.  $u_{ijkd} = 212 \ u_{ijk} - u_{i0}$ .

After the area in which the object k locates is determined, 214 the approximate position in the area can be estimated according 215 to the image coordinates  $u_{ijk}$ . In addition, the areas  $S_3$  and  $S_4$  216 can be divided into subareas using auxiliary point  $Q_1$ , which is 217 the intersection of line  $B_3B_4$  and the  $Z_h$ -axis. The angle  $\beta$  is 218 defined as  $\angle B_2C_2Q_1$ , which is given as follows:

$$\beta = \text{atan}(2z_h/D) + \alpha_1 - \pi/2.$$
 (13)

The horizontal coordinate of point  $Q_1$  in the first image of 219 camera  $C_{a2}$  can be estimated as follows since it is in proportion 220 to the imaging angle:

$$u_{21q} = u_{211}\beta/(\alpha_1 - \alpha_2) \tag{14}$$

where  $u_{21q}$  and  $u_{211}$  are the horizontal coordinates of point  $Q_1$  222 and the reference object in the first image of camera  $C_{a2}$ .

Similarly,  $u_{12q}$ , the horizontal coordinate of point  $Q_1$  in the 224 second image of camera  $C_{a1}$ , can be estimated. Then, the areas 225 such as  $S_3$ ,  $S_4$ ,  $S_5$ ,  $S_6$ ,  $S_9$ , and  $S_{10}$  can be further divided using 226  $u_{21q}$  and  $u_{12q}$ .

The error analysis is focused on the errors caused by the 229 yawing mechanism for the two cameras.

For the model in Section II-B, the relative error can be 231 calculated via the derivative of (2), i.e.,

$$dz_h/z_h = dD/D - 2d\alpha_1/\sin(2\alpha_1) \tag{15}$$

where dD is the error in D, and  $d\alpha_1$  is the error in  $\alpha_1$ . 233 Generally,  $\alpha_1 \neq 0$ . In the case of very little  $\alpha_1$ ,  $\sin(2\alpha_1)$  will 234 converge to  $2\alpha_1$ . Thus, (15) can be rewritten as 235

$$dz_h/z_h \approx dD/D - d\alpha_1/\alpha_1 \le |dD/D| + |d\alpha_1/\alpha_1|.$$
 (16)

From (16), it is easy to find that the relative error in  $z_h$  is 236 proportional to relative errors dD/D and  $d\alpha_1/\alpha_1$ . For example, 237 when the relative errors in D and  $\alpha_1$  are 1%, the relative error 238 in  $z_h$  is not more than 2%.

For the model in Section II-C, the relative error can be 240 calculated via the derivative of (4), i.e.,

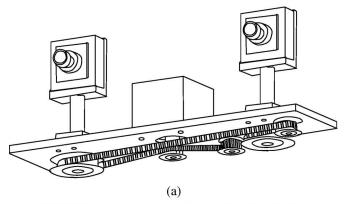

$$\frac{dz_h}{z_h} = \frac{dD}{D} - \frac{(\cos\alpha_2/\cos\alpha_1)d\alpha_1 + (\cos\alpha_1/\cos\alpha_2)d\alpha_2}{\sin(\alpha_1 + \alpha_2)}.$$
(17)

In general,  $\alpha_1 > 0$  and  $\alpha_2 > 0$ ; therefore,  $\alpha_1 + \alpha_2 \neq 0$ . If 242  $\alpha_1$  and  $\alpha_2$  are small enough, then (17) can be rewritten as 243 follows:

$$dz_h/z_h \approx dD/D - d(\alpha_1 + \alpha_2)/(\alpha_1 + \alpha_2)$$
  
 
$$\leq |dD/D| + |d(\alpha_1 + \alpha_2)/(\alpha_1 + \alpha_2)|.$$
 (18)

If  $d\alpha_1$  and  $d\alpha_2$  are taken as the same, then (17) degenerates 245 to (16).

The term  $|d(\alpha_1 + \alpha_2)/(\alpha_1 + \alpha_1)|$  would be large if the 247 errors  $d\alpha_1$  and  $d\alpha_2$  are large since the optical axes of the two 248 cameras are not parallel in the initial state. In the initial state, the 249 nonparallel axes can be taken as the results that the optical axes 250 are yawed with initial angles. Hence, it is necessary to calibrate 251 the initial angles of the optical axes relative to the  $Y_hZ_h$  plane. 252 In fact, the influence of the principal point on the errors of  $z_h$  253 can be taken in the same way as for that of the initial angles and 254 can be reduced via initial angle calibration.

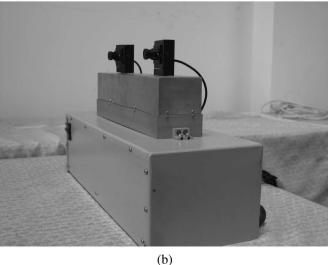

Fig. 7. Experiment system. (a) Principle scheme. (b) Actual system.

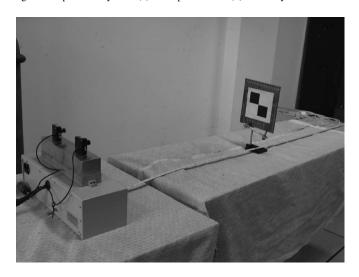

Fig. 8. Scene of calibration for initial optical directions.

From (5), the relative error  $dx_h/z_h$  is deduced as follows:

$$\frac{dx_h}{z_h} = \frac{dz_h}{z_h} \tan \alpha_1 - \frac{dD}{2z_h} + \frac{d\alpha_1}{(\cos \alpha_1)^2}.$$
 (19)

257 In (19), the terms containing  $dD/z_h$  and  $d\alpha_1$  are so small 258 that they can be neglected. It is certain that  $dx_h/z_h$  is smaller 259 than  $dz_h/z_h$  since  $\tan\alpha_1<1$ .

From (9) to (11), the relative error  $dy_h/z_h$  is deduced as 260 follows:

$$\frac{dy_{h}}{z_{h}} = \frac{1}{2} \frac{v_{1d}}{u_{1d}} \left[ \frac{\sin(\alpha_{1} - \alpha_{2})}{\cos \alpha_{1}} \frac{dz_{h}}{z_{h}} + \frac{\cos \alpha_{2} d\alpha_{1} - \cos(\alpha_{1} - \alpha_{2}) \cos \alpha_{1} d\alpha_{2}}{(\cos \alpha_{1})^{2}} \right]$$

$$+ \frac{1}{2} \frac{v_{2d}}{u_{2d}} \left[ \frac{\sin(\alpha_{1} - \alpha_{2})}{\cos \alpha_{2}} \frac{dz_{h}}{z_{h}} + \frac{\cos(\alpha_{1} - \alpha_{2}) \cos \alpha_{2} d\alpha_{1} - \cos \alpha_{1} d\alpha_{2}}{(\cos \alpha_{2})^{2}} \right]$$

$$+ \frac{1}{2} \frac{dv_{1d}}{u_{1d}} \frac{\sin(\alpha_{1} - \alpha_{2})}{\cos \alpha_{1}} + \frac{1}{2} \frac{dv_{2d}}{u_{2d}} \frac{\sin(\alpha_{1} - \alpha_{2})}{\cos \alpha_{2}} - \frac{1}{2} \frac{v_{1d} du_{1d}}{u_{1d}^{2}} \frac{\sin(\alpha_{1} - \alpha_{2})}{\cos \alpha_{1}} - \frac{1}{2} \frac{v_{2d} du_{2d}}{u_{2d}^{2}} \frac{\sin(\alpha_{1} - \alpha_{2})}{\cos \alpha_{2}} - \frac{1}{2} \frac{v_{2d} du_{2d}}{u_{2d}^{2}} \frac{\sin(\alpha_{1} - \alpha_{2})}{\cos \alpha_{2}}$$

$$(20)$$

where  $du_{1d}$ ,  $dv_{1d}$ ,  $du_{2d}$ , and  $dv_{2d}$  are the errors in  $u_{1d}$ ,  $v_{1d}$ , 262  $u_{2d}$ , and  $v_{2d}$ , respectively.

The terms such as  $[\cos\alpha_2 d\alpha_1 - \cos(\alpha_1 - \alpha_2)\cos\alpha_1 d\alpha_2]/264$   $(\cos\alpha_1)^2$  and  $[\cos(\alpha_1 - \alpha_2)\cos\alpha_2 d\alpha_1 - \cos\alpha_1 d\alpha_2]/(\cos\alpha_2)^2$  265 in (20) are negligible when the angles  $\alpha_1$  and  $\alpha_2$  are small 266 enough. Terms with  $du_{1d}$  and  $du_{2d}$  are negligible after the 267 initial angles of the optical axes are calibrated. Then, (20) can 268 be rewritten as follows:

$$\frac{dy_h}{z_h} \approx \frac{1}{2} \left[ \frac{v_{1d}}{u_{1d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} + \frac{v_{2d}}{u_{2d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_2} \right] \frac{dz_h}{z_h} + \frac{1}{2} \left[ \frac{dv_{1d}}{u_{1d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_1} + \frac{dv_{2d}}{u_{2d}} \frac{\sin(\alpha_1 - \alpha_2)}{\cos \alpha_2} \right]. \tag{21}$$

It is found from (21) that  $dy_h/z_h$  is smaller than  $dz_h/z_h$  since 270  $\sin(\alpha_1 - \alpha_2)/\cos\alpha_1 \ll 1$  and  $\sin(\alpha_1 - \alpha_2)/\cos\alpha_2 \ll 1$  when 271  $v_{1d}$  and  $v_{2d}$  are accurate,  $u_{1d}$  and  $u_{2d}$  are not very small, and  $\alpha_1$  272 and  $\alpha_2$  are small enough. In the case of very small  $u_{1d}$  and  $u_{2d}$ , 273 the error  $dy_h/z_h$  will be large. An alternative method to solve 274 this problem is given as follows. When  $y_{c1}$  is calculated with 275 (9),  $u_{1d}$  and  $v_{1d}$  are generated in the condition  $\alpha_2 = 0$ . While 276  $y_{c2}$  is calculated with (10),  $u_{2d}$  and  $v_{2d}$  are generated in the 277 condition  $\alpha_1 = 0$ . In the case that there are large errors in  $v_{1d}$  278 and  $v_{2d}$ , the error  $dy_h/z_h$  is apparent since it is proportional 279 to  $dv_{1d}$  and  $dv_{2d}$ . In addition,  $k_x$  and  $k_y$  are very close for 280 most cameras. Generally, the value of  $k_y/k_x$  is close to 1 with 281 an error of less than 2%. For example, when  $\alpha_1 = \pi/6$ ,  $\alpha_2 = 282$  $\pi/12$ ,  $u_{1d} = 40$ ,  $v_{1d} = 50$ ,  $u_{2d} = 45$ ,  $v_{2d} = 60$ ,  $dz_h/z_h = 2\%$ , 283  $dv_{1d} = 50$ , and  $dv_{2d} = 50$ , the relative error  $dy_h/z_h$  is not more 284 than 1.1%. It means that the relative error  $dy_h/z_h$  is not very 285 sensitive to the cameras' intrinsic parameters.

From (16) and (18), it should be noted that the term dD/D 289 is a small constant since  $D \gg dD$ . Thus, the relative errors in 290  $\alpha_1$  and  $\alpha_2$  may be the main source for the relative error in  $z_h$ . 291

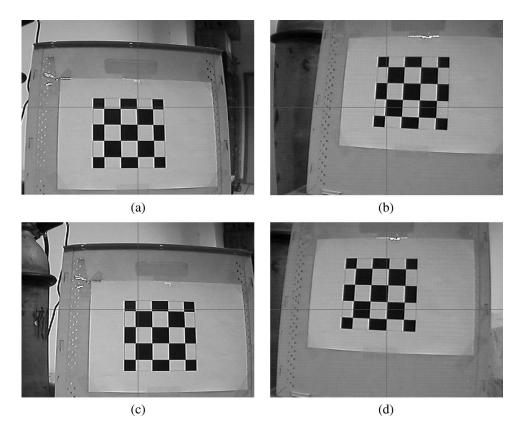

Fig. 9. Some images of the object to be measured in experiments. (a) Image of chessboard in  $C_{a1}$  and (b) image in  $C_{a2}$  at the first step. (c) Image in  $C_{a1}$  and (d) image in  $C_{a2}$  at the second step.

292 The initial yawing angles of the cameras are assumed to be 293 zero, and the optical axes are assumed to be parallel. In fact, 294 the actual initial yawing angles will not be zero. As mentioned 295 in Section II-B, the optical axes of two cameras are just almost 296 parallel in the initial state. Obviously, there exist system errors 297 denoted as  $\alpha_{e1}$  and  $\alpha_{e2}$  for  $\alpha_1$  and  $\alpha_2$ , respectively, in the initial 298 state. The calibration of the initial directions of optical axes is 299 to find the values of  $\alpha_{e1}$  and  $\alpha_{e2}$ .

Taking  $\alpha_{e1}$  and  $\alpha_{e2}$  into account, (4) is rewritten as follows:

$$\tan(\alpha_1 + \alpha_{e1}) + \tan(\alpha_2 + \alpha_{e2}) = D/z_h.$$
 (22)

With the expansion and simplification of (22), the following 302 equation is derived:

$$a_1xy + a_2x + a_3y + a_4 = 0 (23)$$

303 where

$$\begin{cases} x = \tan \alpha_{e1} \\ y = \tan \alpha_{e2} \\ a_1 = \tan \alpha_1 + \tan \alpha_2 + \tan \alpha_1 \tan \alpha_2 D/z_h \\ a_2 = \tan \alpha_1 \tan \alpha_2 - \tan \alpha_1 D/z_h - 1 \\ a_3 = \tan \alpha_1 \tan \alpha_2 - \tan \alpha_2 D/z_h - 1 \\ a_4 = D/z_h - \tan \alpha_1 - \tan \alpha_2. \end{cases}$$
(24)

Formula (23) is a nonlinear equation for parameters x and y. 305 In the calibration, a block is placed in front of the two cameras; 306 the distance from the block to the midpoint of the two cameras 307 can be measured. The cameras are yawed to have  $\alpha_1$  and  $\alpha_2$  308 as described in Section II-C. Changing the block's position a

number of times, a series of nonlinear equations as (23) are 309 formed.

$$f_i(x,y) = a_{1i}xy + a_{2i}x + a_{3i}y + a_{4i}$$
 (25)

where  $a_{1i}$  to  $a_{4i}$  are the coefficients  $a_1$  to  $a_4$  computed from 312 (24) at the *i*th sampling of calibrating data.

Then, an objective function F(x,y) can be defined as 314 follows:

$$F(x,y) = \sum_{i=1}^{n} f_i^2(x,y)$$
 (26)

where n is the sampling times, i.e., the groups of data formed 316 for calibration.

Now, the solution of the nonlinear (23) is converted to an 318 optimization problem to find the optimal parameters x and y to 319 make F(x,y) be minimum. As it is known, the quasi-Newton 320 method is efficient to solve this problem.

After the above calibration, the parameters  $u_{10}$  and  $u_{20}$  in (9) 322 and (10) can be evaluated to the image horizontal coordinates 323 of the image center. 324

### VI. EXPERIMENTS AND RESULTS

325

An experiment system was designed as shown in Fig. 7, in 326 which Fig. 7(a) was its principle scheme, and Fig. 7(b) was the 327 actual system. It consisted of two miniature cameras that could 328 AQ1 be simultaneously yawed in opposite directions. A step motor 329

330 was employed to drive the rotation of cameras through the belt 331 and gears. The system was adjusted so that the optical axes of 332 the two cameras were almost parallel initially. The distance be-333 tween the two cameras was 150 mm. The rotational resolution 334 of the two cameras was  $2\pi/25\,600 = 2.45 \times 10^{-4}$  rad.

335 A series of measurement experiments were conducted with 336 the visual system, as shown in Fig. 7(b). First, the initial 337 directions of the optical axes of two cameras were calibrated 338 with the method described in Section V. A scene of optical 339 initial direction calibration was given in Fig. 8. The results were 340  $\alpha_{e1}=0.0578$  rad and  $\alpha_{e2}=-0.0254$  rad. Then, the measure-341 ment method, as described in Section II-C, was employed in the 342 visual measuring experiments.

#### 343 A. Chessboard Measurement

An experiment to measure the blocks in a chessboard was 345 designed to test the effectiveness of the proposed method and 346 system. In the visual measuring experiment, the cameras were 347 yawed to make the horizontal imaging coordinates of the fea-348 ture point be equal to those of the image plane centers of the two 349 cameras separately for each point to be measured in Cartesian 350 space. As described in Section II-C, the cameras were yawed in 351 two steps, and two yawing angles  $\alpha_1$  and  $\alpha_2$  were generated. In 352 Fig. 9, the images captured by the two cameras for the measure 353 of a point were given. Fig. 9(a) was an image of chessboard 354 in  $C_{a1}$ , Fig. 9(b) an image in  $C_{a2}$  at the first step, Fig. 9(c) 355 an image in  $C_{a1}$ , and Fig. 9(d) an image in  $C_{a2}$  at the second 356 step. The image size was  $640 \times 480$  in pixel, and its center was 357 [320, 240]. In the experiment,  $u_{10}$  and  $u_{20}$  were evaluated to 358 be 320;  $v_{10}$  and  $v_{20}$  were evaluated to be 240. It can be seen 359 that the images have large distortions, and the optical axes of 360 the two cameras might not be parallel.

16	79.5523	52.1520	522.6241

The image offset coordinates from the image center and the 361 yawing angles for cross points in the chessboard were listed 362 in Table I. It can be seen that the offset coordinates  $u_{1d}$  and 363  $u_{2d}$  of points 2, 6, 10, and 14 were very small. As analyzed 364 at the end of Section IV, the calculation of  $y_{c1}$  and  $y_{c2}$  would 365 introduce large errors. To deal with this problem, several data 366 were captured for the four points above, that is,  $u_{1d}$  and  $v_{1d}$  367 were generated in the condition  $\alpha_2=0$ , and  $u_{2d}$  and  $v_{2d}$  were 368 generated in the condition  $\alpha_1=0$ .

The coordinates  $z_h$  and  $x_h$  in frame H were computed using 370 (4) and (5) according to  $\alpha_1$  and  $\alpha_2$  modified with  $\alpha_{e1}$  and  $\alpha_{e2}$ . 371 With the image coordinates and yawing angles listed in Table I, 372  $y_{c1}$  and  $y_{c2}$  were calculated via (9) and (10), except for points 2, 373 6, 10, and 14. It should be noted that the term  $\alpha_1 - \alpha_2$  in (9) and 374 (10) denoted the relative rotation angle. Thus,  $\alpha_1$  and  $\alpha_2$  in the 375 numerators of (9) and (10) did not need to be modified with  $\alpha_{e1}$  376 and  $\alpha_{e2}$ .  $\alpha_1$  in the denominator of (9) and  $\alpha_2$  in the denominator 377 of (10) were the yawing angles relative to the axis  $Z_h$ , and they 378 need to be modified with  $\alpha_{e1}$  and  $\alpha_{e2}$ . For points 2, 6, 10, and 379 14,  $y_{c1}$  was calculated via (9) with the image offset coordinates 380 in Table II,  $\alpha_1$  in Table I, and  $\alpha_2 = 0$ .  $y_{c2}$  was calculated 381 for these points via (10) with the image offset coordinates in 382 Table II,  $\alpha_2$  in Table I, and  $\alpha_1 = 0$ . The average value of  $y_{c1}$  and 383  $y_{c2}$  was taken as the coordinate  $y_h$ . The experimental results to 384 measure a chessboard were listed in Table III. The data were 385 the 3-D positions of the cross points on the chessboard in the 386 vision system frame H. They were also shown in Fig. 10(a) 387 for convenience of evaluation. The actual width and height for 388 each block in the chessboard were both 30 mm. The measured 389 width and height computed from the distances between any two 390 adjacent cross points in the pattern were listed in Table IV and 391 also shown in Fig. 10(b). Its mean is 30.3 mm, and the standard 392 deviation was 0.677 mm. In addition, Fig. 10(b) also displayed 393 the difference of  $y_{c1}$  and  $y_{c2}$  computed from (9) and (10). It 394 can be found that the differences were stable. Therefore, the 395 differences can be considered as the offsets resulting from the 396 nonparallel axes of the two cameras, in respect of an object in 397 some depth  $Z_h$ .

From Fig. 10 and Tables III and IV, it can be found that 399 the measuring accuracy with the proposed visual system and 400

401 method was satisfactory even if the camera lens had large 402 distortion.

#### 403 B. Comparison With Stereovision

404 To compare the proposed method with the traditional 405 stereovision method, the two cameras were well calibrated 406 with Zhang's calibration method [6]. The intrinsic parameters 407 of the cameras were as follows:  $k_{x1}=834.82771,\ k_{y1}=408.815.41740,\ u_{10}=303.8,\ v_{10}=306.3,\ k_{x2}=850.45548,$  409  $k_{y2}=833.29453,\ u_{20}=345.1,\$ and  $v_{20}=197.3.$  The 410 distortion factors of the lens in the radial direction were 411  $k_{c1}=-0.38741$  and  $k_{c2}=-0.30938$  for cameras  $C_{a1}$  and 412  $C_{a2}$  separately. The extrinsic parameter matrix  $^{c1}T_{c2}$ , i.e., the

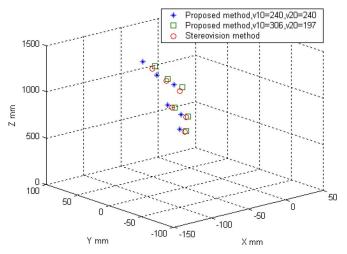

Fig. 11. Experiment results with the proposed method and the stereovision method.

pose of camera  $C_{a2}$  relative to camera  $C_{a1}$ , was well calibrated 413 as given in (27) when the two cameras were at the initial 414 positions, i.e.,

$${}^{c1}T_{c2} = \begin{bmatrix} 0.9995 & -0.0236 & -0.0222 & -150.9556 \\ 0.0234 & 0.9997 & -0.0091 & -5.1851 \\ 0.0224 & 0.0086 & 0.9997 & 2.2226 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$
(27)

The experiment scene was similar to that of the initial optical 417 direction calibration, as given in Fig. 8. The intersection be- 418 tween the two black blocks on a target, as shown in Fig. 8, was 419 selected as the point P to be measured. When the target was 420 placed at a position in front of the visual system, the two cam- 421 eras were yawed to initial directions and captured the target's 422 images. The Cartesian space position of point P in the frame 423

456

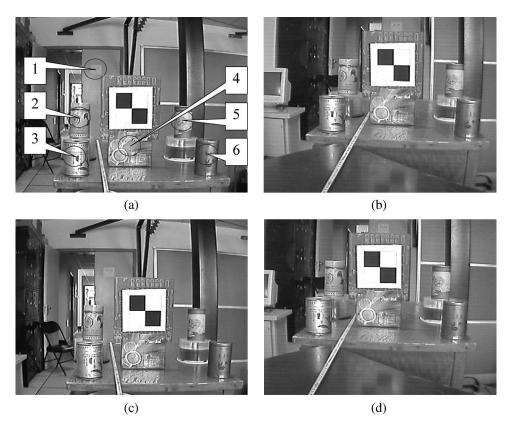

Fig. 12. Images of the objects in experiments. (a) Image in  $C_{a1}$  and (b) image in  $C_{a2}$  at the first step. (c) Image in  $C_{a1}$  and (d) image in  $C_{a2}$  at the second step.

424 of camera  $C_{a1}$  was calculated with the traditional stereovision 425 method. The coordinates of point P in frame H were obtained 426 via transformations including the rotation with  $\alpha_{e1}$  around axis 427  $y_{c1}$  and the translation with D/2 along axis  $x_{c1}$ . Then, the two 428 cameras were yawed with a tracking algorithm in two steps to 429 generate  $\alpha_1$  and  $\alpha_2$ , and the coordinates of point P in frame 430 H were computed with the proposed method as described in 431 Section II-C. The procedure above was repeated while the target 432 was placed at different positions in front of the visual system, 433 and six groups of visual measuring results were formed as given 434 in Tables V and VI. They are also displayed in Fig. 11 for 435 assessing convenience.

436 The results from the stereovision method were computed 437 using the intrinsic and extrinsic parameters of the two cam-438 eras, as given above in this section. The lens distortion in 439 the radial direction was also taken into account. The results 440 from the proposed method did not use the parameters such 441 as  $k_{x1}$ ,  $k_{y1}$ ,  $k_{x2}$ , and  $k_{y2}$ , and the distortion factors  $k_{c1}$  and 442  $k_{c2}$ . The y-coordinates of the measured positions with the 443 proposed method in Table V were computed in the condition 444 that  $u_{10}=320$ ,  $v_{10}=306.3$ ,  $u_{20}=320$ , and  $v_{20}=197.3$ . The 445 y-coordinates in Table VI were computed with the proposed 446 method in the condition that  $u_{10}=320$ ,  $v_{10}=240$ ,  $u_{20}=447\ 320$ , and  $v_{20}=240$ . In other words, the results in Table VI 448 were calculated in the case that the intrinsic parameters of the 449 cameras were supposed to be not available.

450 From Fig. 11 and Tables V and VI, it can be found that 451 the measuring accuracy with the proposed visual system and 452 method was very close to that with the stereovision method, 453 even if the cameras' intrinsic parameters were not employed,

and the large distortion in the camera lens was not taken into 454 account in the proposed method.

## C. Relative Positioning

To verify the effectiveness of the relative positioning method 457 for multiple objects, an experiment was conducted. A board 458 target with two black blocks, as shown in Fig. 8, was selected 459 as the main object, which was surrounded by other objects. The 460 intersection of the two blocks was selected as the feature point. 461 As described in Section II-C, the cameras were yawed with a 462 tracking algorithm in two steps. In the first step, the cameras 463 were yawed to make the feature point be at the horizontal center 464 in the image of camera  $C_{a1}$ . In the second step, the cameras 465 were yawed to make the feature point be at the horizontal center 466 in the image of camera  $C_{a2}$ .  $\alpha_1$  and  $\alpha_2$  were generated as 467  $\alpha_1 = 0.08$  and  $\alpha_2 = 0.0349$ . Each camera captured an image 468 at the end of each step. Four frames of images were captured at 469 the two measuring positions for the two cameras, as shown in 470 Fig. 12.

The six objects to be measured were represented by their 472 image centers. The image coordinates  $u_{11k}$ ,  $u_{12k}$ ,  $u_{21k}$ , and 473  $u_{22k}$ ,  $k=1,2,\ldots,6$ , for the six objects extracted from the four 474 images captured by the two cameras in the two steps, were 475 listed in Table VII. Applying (12) to the image coordinates of 476 the six objects, we had the areas that the objects belonged to. In 477 other words, the approximate positions of the objects relative to 478 the main object were obtained, as listed in Table VII. It is easy 479 to check the correctness of the relative positioning results via 480 comparison to their actual positions.

489

519

TABLE VII
IMAGE COORDINATES OF THE OBJECTS AND THEIR AREAS LOCATED

Object k	$u_{11k}$	$u_{12k}$	$u_{22k}$	$u_{22k}$	Area belonged to	
					Measured	Actual
1	220	256	363	327	$S_1$	$S_1$ , left, behind
2	177	213	227	190	$S_{11}$	$S_{11}$ , left
3	165	202	186	148	$S_{11}$	$S_{11}$ , left
4	314	353	352	317	$S_4$	$S_4$ , left, front
5	463	500	527	490	$S_{12}$	$S_{12}$ , right
6	532	569	560	525	$S_{12}$	$S_{12}$ , right

482 In addition, experiments with the proposed visual system 483 and method, in Sections VI-A and B, also gave evidence that 484 the measuring precision would be heavily influenced by the 485 directions of the optical axes of the two cameras in the initial 486 state. Therefore, the calibration of the initial directions of the 487 optical axes of the two cameras is important to ensure the 488 precision in practical visual measurements.

#### VII. CONCLUSION

490 A new active visual system is developed, which consists 491 of two cameras and a two-DOF mechanical platform. Two 492 cameras are mounted on the platform, which can pitch and yaw. 493 The two cameras can be simultaneously adjusted in opposite di-494 rections. With pitching and yawing of the platform, and relative 495 yawing of the cameras, the object's images can be adjusted to 496 the center areas of the image planes of the two cameras. Then, 497 the position of the object is determined with the geometrical 498 information of the visual system. Furthermore, a more general 499 visual model is proposed. It consists of two cameras that can 500 yaw in opposite directions. In two steps, the object's images 501 are adjusted to the center areas of the image planes of the two 502 cameras separately. The position of an object can be calculated 503 with the yawing angles and the image coordinates of the object 504 in the two steps.

The visual system proposed in this paper is based on bionic 506 vision and is insensitive to the intrinsic parameters of the 507 camera. Experiment results showed that the measuring accuracy 508 with the proposed visual system and method was very close 509 to that with a stereovision method, even if the actual intrinsic 510 parameters of the cameras were not available, and large dis-511 tortion in the camera lens was not taken into account in the 512 proposed method. Low efficiency in measuring multiple objects 513 is its main limitation. However, the cases with the tracking or 514 measuring of multiple objects are uncommon in a visual control 515 system.

Future work will be focused on its applications such as 517 navigation, object tracking, approaching, and grasping for hu-518 manoid robots.
